ABSTRACT

Chilled water systems used in the industry and on board ships are critical for safe and reliable operation. It is hence important to understand the fundamental physics of these systems. This paper focuses in particular on a critical part of the automation system, namely, actuators and valves that are used in so-called “smart valve” systems. The system is strongly nonlinear, and necessitates a nonlinear dynamic analysis to be able to predict all critical phenomena that affect effective operation and efficient design. The derived mathematical model includes electromagnetics, fluid mechanics, and mechanical dynamics. Nondimensionalization has been carried out in order to reduce the large number of parameters to a few critical independent sets to help carry out a broad parametric analysis. The system stability analysis is then carried out by the aid of the tools from nonlinear dynamic analysis. This reveals that the system is unstable in a certain region of the parameter space. The system is also shown to exhibit crisis and chaotic responses; this is characterized using Lyapunov exponents and power spectra. Knowledge and avoidance of these dangerous regimes is necessary for successful and safe operation.

INTRODUCTION

Modeling and designing accurate shipboard machinery systems has received much attention as one of the important challenges that needs to be overcome for supporting the next generation Naval machinery automation requirements [1]. Typical automation systems used in the US Navy consist of actuators, sensors, controllers, valves, piping, electrical cabling and communication wiring. Many types of actuator-valve systems are in use [2, 3].

In general, these systems are nonlinear and exhibit nonlinear phenomena such as multiple steady solutions, bifurcations, multi-frequency responses, and chaotic dynamics. All of these phenomena have been observed in practice but cannot be explained even qualitatively by traditional linear theories used in engineering practice.

This paper focuses in particular on a critical part of the automation system, namely, actuator-valve systems that form an important part of what are termed “smart valve” systems. All of these systems are nonlinear and need to be analyzed as such. Nonlinear dynamic analysis of such an interdisciplinary system is not trivial, but needs to be investigated in order to predict possible critical phenomena including chaos and its routes.

Specific work related to the system considered here is somewhat difficult to find; however, there has indeed been much research in related areas and is discussed here. Important nonlinear phenomena in electromechanical systems such as chaos have received considerable attention by researchers. Belato et al. [4] analyzed chaotic vibrations of an electromechanical system which includes a nonlinear dynamic system consisting of a simple pendulum whose support point is vibrated along a horizontal guide by a two bar linkage driven by a DC motor with limited power.
Nonlinear dynamic analysis of a micro electromechanical system (MEMS) has been carried out by Xie et al. [5] based on an invariant manifold method proposed by Boivin et al. [6]. Ge and Lin [7] have studied dynamical analysis of electromechanical gyrostat system subjected to external disturbance.

Chaotic responses are distinguishable by sensitivity to initial conditions which are examined in this paper. Power spectra and Lyapunov exponents are also helpful to identify chaotic system responses since they exhibit a broadband power spectrum, and one or more positive Lyapunov exponents must be observed [8].

The first part of the paper deals with a high-fidelity mathematical model, and the second part deals with nonlinear dynamic analysis of the system. This paper follows on the previous work carried out by the authors [9].

MATHEMATICAL MODELING

The system consists of a solenoid actuator energized by an electric voltage (DC or AC) which moves a plunger. The plunger is connected to a butterfly valve through a rack and pinion arrangement as shown in Fig. 1. The magnetic flux generates the needed electromagnetic force to move the plunger and subsequently results in the rotation of the butterfly valve by the coupled rack and pinion mechanism.

An ideal pressure angle is assumed for the rack and pinion mechanism with an assumption of no backlash of the gears. The valve controls the flow in a pipe and is hence subject to hydrodynamic forces.

Electromagnetics

The magnetic force is calculated using the reluctance method [9] as follows.

$$ F_m = \frac{R_2 N^2 i^2}{2(R_1 + R_2(g_0 - x))^2} $$  \hspace{1cm} (1)

where, $g_0$ indicates the maximum stroke of the plunger, $x$ is the displacement of solenoid plunger, and, $R_1$ and $R_2$ are the reluctances of the magnetic flux paths. A simple circuit model leads to the following mathematical model.

$$ \frac{di}{dt} = \frac{(V - Ri)(R_1 + R_2(g_0 - x))}{N^2} - \frac{R_2 i \dot{x}}{(R_1 + R_2(g_0 - x))} $$ \hspace{1cm} (2)

Fluid Mechanics

Analysis must be done on the hydrodynamic ($T_h$), bearing ($T_b$), and seating ($T_s$) torques as they are highly nonlinear functions affecting the valve rotation angle. The torque terms are given as follows [10–14].

$$ T_h = \frac{8 \rho T_c D_v^3 V_0^2}{3 \pi} \frac{4}{[C_{cc}(1 - \sin \alpha)]^2} \left(\frac{V J}{V_0}\right)^2 $$ \hspace{1cm} (3)

$$ T_b = -\frac{\pi}{8} \mu D_s D_v^2 \Delta P \text{sign}(\dot{\alpha}) $$ \hspace{1cm} (4)

$$ T_s = C_s D_v^2 $$ \hspace{1cm} (5)

where, $\rho$ is the fluid density; $\alpha$ is the valve rotation angle; $T_c$ indicates the torque coefficient which can be calculated by a table look up for various values of $\alpha$, based on Computational Fluid Dynamics calculations, as shown in Fig. 2; $D_v$ is the pipe diameter; $V_0$ indicates the inlet velocity of flow; $V_J$ is the jet velocity; $C_{cc}$ is the sum of upper and lower contraction coefficients and is shown in Fig. 3; $D_s$ is the stem diameter; $\mu$ indicates the friction coefficient of the bearing area; $C_s$ is the coefficient of the seating area; and,

$$ \Delta P = \frac{1}{2} \rho V_0^2 \left(\frac{V J}{V_0} - 1\right)^2 $$ \hspace{1cm} (6)
indicates the pressure drop across the valve.

**Dynamics**

The dynamical equations of the plunger and butterfly valve can be written as follows (Fig. 4).

\[ m \ddot{x} + c \dot{x} + kx = F_m - F_c \quad (7) \]

\[ J\ddot{\alpha} + b\dot{\alpha} = rF_c + T_h - T_s \text{sign}(\alpha) - T_i \quad (8) \]

Note that \( C_{cc} \) and \( T_c \) are dependent on \( \alpha \). Eqs. (2) and (10) constitute the third order dynamic model for the system.

**NONDIMENSIONALIZATION**

In order to reduce the number of parameters, and to perform a systematic analysis, the nonlinear dynamic equations need to be nondimensionalized. We define the state vector as \( x = [\alpha, \dot{\alpha}, i]^T \), and derive the nondimensionalized state-space equations as follows.

\[ \dot{x}_1 = x_2 \quad (11) \]

\[ \dot{x}_2 = -x_1 - 2\xi x_2 + \frac{\dot{\theta} x_1^2}{(\Delta_1 + \Delta_2(\gamma - x_1))^2} + (x_1 (\beta_1 e^{\gamma x_1} + \beta_2)) - \text{sign}(x_2) (\kappa_1 x_1^2 e^{\kappa_2 x_1} + \kappa_3 e^{\kappa_4 x_1}) - \frac{C_{cc}D_v^2}{\omega_m^2 (J + mr^2)} \quad (12) \]
\[ \dot{x}_3 = \frac{(y - x_3)(\Delta_1 + \Delta_2(y - x_1))}{N^2} - \frac{\Delta_2 x_3}{(\Delta_1 + \Delta_2(y - x_1))} \] (13)

Here,

\[ \omega_{h0} = \sqrt{\frac{kr^2}{J + mr^2}}; \gamma = \frac{g_0}{r}; \Delta_1 = \frac{RR_1}{\omega_{h0}}; \Delta_2 = \frac{RR_2}{\omega_{h0}} \]

\[ \zeta = \frac{(b + cr^2)}{2\omega_{h0}(J + mr^2)}; \vartheta = \frac{rR_2N^2\beta^2R^2}{2\omega_{h0}^4(J + mr^2)} \]

The values of \( \beta_1, \beta_2, \alpha, \kappa_1, \kappa_2, \kappa_3 \) and \( \kappa_4 \) are calculated based on fitting the torques to the following functions with least square error.

\[ T_{\text{hnd}} = \beta_1 e^{\kappa_2} + \beta_2 e^{\kappa_3} \] (14)

\[ T_{\text{hnd}} = \kappa_1 e^{\kappa_2} + \kappa_3 e^{\kappa_4} \] (15)

**NONLINEAR ANALYSIS**

The model has twelve nondimensional parameters; the analysis presented in this paper assumes specific values for ten of them as shown in Table 1; these values are based on realistic parameter values for an industrial system. Two parameters, \( \vartheta \) and \( \zeta \), are considered to vary over a range of values.

The sign function is replaced by a differentiable function to make the linearization process easier. A smooth approximation of the sign function is,

\[ \text{sign}(x_2) \approx \tanh(Kx_2) \] (16)

where, \( k \) can be tuned to get a good approximation; we used \( k = 1 \) in this analysis.

The Jacobian matrix for the system can be calculated as follows.

\[ J = \begin{bmatrix}
0 & 1 & 0 \\
A_0 & A_1 & \frac{2\Delta x_3}{(\Delta_1 + \Delta_2(y - x_1))} \\
B_0 & \frac{2\Delta x_3}{(\Delta_1 + \Delta_2(y - x_1))} & C_0
\end{bmatrix} \] (17)

where,

\[ A_0 = \frac{2\Delta x_3^2}{(\Delta_1 + \Delta_2(y - x_1))^2} + \beta_1 e^{a_{x10}}(1 + a_{x10}) \]

**TABLE 1. Nondimensional parameters**

| \( \beta_1 \) | \( 7 \times 10^{-4} \) | \( a \) | \( 5.2764 \) |
| \( \beta_2 \) | 0.44 | \( \gamma \) | 1.8 |
| \( \kappa_1 \) | \( 1 \times 10^{-7} \) | \( \kappa_2 \) | 13.62 |
| \( \kappa_3 \) | -0.5 | \( \zeta \) | varies |
| \( \kappa_4 \) | -13 | \( \vartheta \) | varies |
| \( \Delta_1 \) | 536 |
| \( \Delta_2 \) | \( 1 \times 10^4 \) |

\[ + \beta_2 - 1 \]

\[ A_1 = -2\zeta - K(1 - \tanh^2 Kx_{20})(\kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}}) \] (18)

\[ B_0 = -\frac{\Delta_2(x - x_30)}{N^2} - \frac{\Delta_3 x_{20} x_{30}}{(\Delta_1 + \Delta_2(y - x_1))} \] (19)

\[ C_0 = -\frac{\Delta_1 + \Delta_2(y - x_10)}{N^2} - \frac{\Delta_2 x_{20}}{\Delta_1 + \Delta_2(y - x_10)} \] (20)

\[ + \Delta_2 y_{x10} \] (21)

and \([x_{10}, x_{20}, x_{30}]\) is an equilibrium point of the system.

For the linearized system, the characteristic equation becomes

\[ s^3 + 2\zeta \left( \frac{\Delta_1 + \Delta_2(y - x_10)}{N^2} + K \left( \kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}} \right) \right) \]

\[ + \kappa_3 e^{k_{x10}} \]

\[ s^2 + \left( 2\zeta + K(\kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}}) \right) \times \]

\[ \left( \frac{\Delta_1 + \Delta_2(y - x_10)}{N^2} \right) + 1 - (\beta_1 e^{a_{x10}}(1 + a_{x10}) + \beta_2) \]

\[ + \Delta_2 y_{x10} = 0 \] (22)

Using Routh-Hurwitz criteria, one is able to judge the system’s linear stability behavior. The asymptotical stability requirements of the system can then be determined as follows.

\[ \frac{2\Delta x_3^2}{(\Delta_1 + \Delta_2(y - x_1))} + \beta_1 e^{a_{x10}}(1 + a_{x10}) + \beta_2 < 1 \] (23)

\[ \frac{4\zeta^2(\Delta_1 + (y - x_{10})\Delta_2)}{N^2} + \frac{2\zeta(\Delta_1 + (y - x_{10})\Delta_2)^2}{N^4} \]

\[ + \frac{2\zeta^2\Delta_2}{N^2(\Delta_1 + (y - x_{10})\Delta_2)^2} + 4\zeta K(\kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}}) \]

\[ \times \left( \frac{\Delta_1 + (y - x_{10})\Delta_2}{N^2} \right) + 2\zeta + K(\kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}}) \]

\[ \times \left( \frac{\Delta_1 + (y - x_{10})\Delta_2}{N^4} \right) + K^2(\kappa_1 x_{10} e^{k_{x10}} + \kappa_3 e^{k_{x10}})^2 \]

\[ \begin{align*}
&\times \frac{(\gamma - x_{10})\Delta_1}{N^2} + K\left(k_1x_{10}^2e^{k_2x_{10}} + k_3e^{k_4x_{10}}\right) \\
&> 2\zeta(\beta_1 e^{\alpha x_{10}}(1 + \alpha x_{10}) + \beta_2) + K\left(k_1x_{10}^2e^{k_2x_{10}} + k_3e^{k_4x_{10}}\right) \\
&\times (\beta_1 e^{\alpha x_{10}}(1 + \alpha x_{10}) + \beta_2) \\
&\end{align*} \]

(24)

It can be shown from Eq. 23 that the system reveals an unstable response unless \( k \) is large enough which reduce the value of \( \beta_2 \).

Eq. 24 yields a comprehensive relationship to examine the system stability by varying the critical parameters such as \( \zeta \) (equal viscous damping) and \( \vartheta \) (magnetic force parameter).

Fig. 5 illustrates the range of \( \zeta \) vs. \( \vartheta \) obtained from the calculated stability criteria where the stable and unstable regions can be distinguished. A confirmation of the stability map is shown in Fig. 6 revealing the stable behavior of the system for \( \zeta = 0.5 \) and \( \vartheta = 4.8 \times 10^5 \); the system’s unstable behavior can be observed from Fig. 7 where the response diverges to infinity.

Next, we investigate the system responses for variations of \( \zeta \) and \( \vartheta \). Shown in Fig. 8 indicates a trapped chaotic motion between two stable regions using a marginal value of \( \zeta \).

The Lyapunov exponents of such a motion shown in Fig. 9 confirm the observed chaotic motion; one positive Lyapunov exponent is distinguishable. Note that the positive value is not big enough to yield a chaotic motion forever and its effects finally will be mitigated by the largest negative value of Lyapunov exponents (\( |\lambda_3| \approx 10|\lambda_1| \)).

Shown in Fig. 10 is the power spectrum indicating noisy characteristic typical of chaotic responses for a certain range of frequencies.

Zeeman [15] defines a catastrophe to be any discontinuous bifurcation. Abraham and Stewart [16] have been more specific and define blue sky catastrophe - a bifurcation in which an entire attractor disappears abruptly from the phase portrait as a control parameter \( \alpha \) passes through its critical value \( \alpha_c \); when such a bifurcation occurs, the dynamical system will make a finite jump to a remote attractor, or diverge to infinity [17].

A small change in the critical value of \( \zeta (0.133) \) yields such a phenomenon (crisis) shown in Fig. 11 where a chaotic attractor abruptly disappears for \( \zeta = 0.1329 \) and diverges to infinity. It can also be validated from Fig. 12 where its Lyapunov exponents, having at least one positive value for a chaotic motion, suddenly disappear.

**CONCLUSION**

This paper developed accurate nonlinear dynamic models of butterfly valves operated by solenoid actuators. Many tools from
nonlinear dynamic analysis were then utilized to investigate the system stability and distinguish between the responses for a set of parameters.

The variations of two critical parameters, $\zeta$ and $\vartheta$, were then studied to establish stability regimes and to investigate harmful nonlinear phenomena such as chaos and crisis.

Lyapunov exponents were calculated displaying one positive value and the power spectrum showed a noisy nature confirming the chaotic nature of the response for a certain period of time. Also observed for some parametric value was a blue sky catastrophe phenomenon, which is distinguishable by the disappeared chaotic attractor and its divergence to infinity when the control parameter passes through its critical value.

Determining the critical range of these parameters is an important step that needs to be taken for safe operation of the system. Current work is focusing on experimental validation of these theoretical results.

**ACKNOWLEDGMENT**

This work was supported by Office of Naval Research Grant (N00014/08/1/0435). The authors are grateful to ONR, and Mr. Anthony Seman III in particular, for the financial support that made this research possible. Thanks are also due to Dr. Stephen Mastro and Mr. Frank Ferrese of Naval Surface Warfare Center (Philadelphia) for valuable help and guidance.
